## 1 Introduction

This vignette investigates comparisons in performance between packages matter and related packages bigmemory [1] and ff [2], which also provide infrastucture for working with larger-than-memory datasets in R.

The examples demonstrated here are chosen because both linear regression and principal components analysis are statistical tasks common to many areas of bioinformatics.

The use of simulated data allows us to explore performance in a situation where file format is not an issue.

> library(matter)

# 2 Linear regression

## 2.1 Using base R

## 2.2 Using bigmemory

## 2.3 Using ff

```
> library(ff)
> library(ffbase)
> data.ff <- ff(filename=paste0(backingpath, "/", backingfile),</pre>
         vmode="double", dim=c(n, p + 1),
         dimnames=list(NULL, c("y", names(b))))
> data.ff <- as.ffdf(data.ff)</pre>
> lm.prof[["ff"]] <- profmem({</pre>
         ff.out <- bigglm(fm, data=data.ff, chunksize=chunksize)</pre>
+ })
> rm(ff.out)
> gc()
> print(lm.prof[["ff"]])
   start (MB) finish (MB) max used (MB) overhead (MB) time (sec)
              393.300 1986.800 1593.500
     392.300
                                                            56.987
```

### 2.4 Using matter

# 3 Principal components analysis

```
> library(irlba)
> set.seed(81216)
> n <- 1.5e6
> p <- 100
> data <- matrix(nrow=n, ncol=p)
> for ( i in 1:10 )
+    data[,i] <- (1:n)/n + rnorm(n)
> for ( i in 11:20 )
+    data[,i] <- (n:1)/n + rnorm(n)
> for ( i in 21:p )
+    data[,i] <- rnorm(n)
> pca.prof <- list()</pre>
```

This again creates a 1.2 GB dataset in memory.

# 3.1 Using base R

First, we demonstrate

## 3.2 Using bigmemory

```
> library(bigalgebra)
> backingfile <- "pca-ex.bin"</pre>
> backingpath <- tempdir()</pre>
> descriptorfile <- "pca-ex.desc"</pre>
> data.bm <- filebacked.big.matrix(nrow=n, ncol=p,</pre>
        backingfile=backingfile,
        backingpath=backingpath,
        descriptorfile=descriptorfile,
         type="double")
> for ( i in seq_len(ncol(data)) )
         data.bm[,i] <- data[,i]</pre>
> rm(data)
> gc()
> mult.bm <- function(A, B) {</pre>
+ if ( is.vector(A) )
                  A \leftarrow t(A)
+ if (is.vector(B))
                 B <- as.matrix(B)
        cbind((A %*% B)[])
> pca.prof[["bigmemory"]] <- profmem({</pre>
          bm.out <- irlba(data.bm, nu=0, nv=2, mult=mult.bm)</pre>
+ })
> rm(bm.out)
> gc()
> print(pca.prof[["bigmemory"]])
   start (MB) finish (MB) max used (MB) overhead (MB) time (sec)
      393.900 406.400 3110.000 2703.600
                                                             15.391
```

## 3.3 Using ff

	Linear regres	sion	Principle component analysis				
Method	Mem. used	Mem. overhead	Time	Method	Mem. used	Mem. overhead	
R matrices + Im	7 GB	1.4 GB	33 sec	R matrices + svd	3.9 GB	2.4 GB	
bigmemory + biglm	4.4 GB	3.9 GB	21 sec	bigmemory + irlba	3.1 GB	2.7 GB	
ff + biglm	1.9 GB	1.6 GB	57 sec	ff + irlba	1.8 GB	1.4 GB	1
matter + bigIm	1 GB	660 MB	47 sec	matter + irlba	890 MB	490 MB	1

Table 1: Comparative performance of *matter* for linear regression and calculation of the first two principal components on simulated datasets of 1.2 GB

Memory overhead is the maximum memory used during the execution minus the memory in use upon completion.

## 3.4 Using matter

```
> library(matter)
> data.m <- matter(paths=paste0(backingpath, "/", backingfile),</pre>
           datamode="double", nrow=n, ncol=p)
> pca.prof[["matter"]] <- profmem({</pre>
          m.out <- irlba(data.m, nu=0, nv=2, fastpath=FALSE)</pre>
+ })
> rm(m.out)
> gc()
> print(pca.prof[["matter"]])
   start (MB)
                 finish (MB) max used (MB) overhead (MB)
                                                               time (sec)
      395.400
                     407.400
                                    893.900
                                                   486.500
                                                                  110.884
```

## 4 Summary

Table 1 demonstrates that *matter* typically uses less memory than both *bigmemory* and *ff*. Additionally, it outperforms *ff* in speed. The reason for *bigmemory*'s superior speed is likely its use of map to map the on-disk data to virtual memory. This allows it to perform faster on datasets that can fit into available memory. However, this also uses more memory, because the much of the data ends up being loaded into memory. A comparison on real datasets that are much larger than memory (in the vignette "Supplementary 2 - 3D mass spectrometry imaging case study") demonstrate the *matter* can be faster than *bigmemory* on datasets too large to be fully loaded into memory.

## 5 Session info

- R version 3.5.1 Patched (2018-07-12 r74967), x86\_64-apple-darwin15.6.0
- Locale: C/en\_US.UTF-8/en\_US.UTF-8/C/en\_US.UTF-8/en\_US.UTF-8
- Running under: OS X El Capitan 10.11.6
- Matrix products: default
- BLAS:
  - /Library/Frameworks/R.framework/Versions/3.5/Resources/lib/libRblas.0.dylib
- LAPACK: /Library/Frameworks/R.framework/Versions/3.5/Resources/lib/libRlapack.dylib
- Base packages: base, datasets, grDevices, graphics, methods, stats, utils
- Other packages: DBI 1.0.0, bigIm 0.9-1, matter 1.8.3
- Loaded via a namespace (and not attached): BiocGenerics 0.28.0, BiocManager 1.30.4, BiocStyle 2.10.0, Matrix 1.2-15, Rcpp 1.0.0, compiler 3.5.1, digest 0.6.18, evaluate 0.12, grid 3.5.1, htmltools 0.3.6, irlba 2.3.2, knitr 1.21, lattice 0.20-38, parallel 3.5.1, rmarkdown 1.11, tools 3.5.1, xfun 0.4, yaml 2.2.0
